Abstract

In complex analysis, the argument principle (or Cauchy's argument principle) relates the difference between the number of zeros and poles of a meromorphic function to a contour integral of the function's logarithmic derivative. The aim of this paper is to explain the concept, but not necessarily the proofs, to someone who has completed the same MCS modules as I did.

1 Argument Principle

1.1 Introduction

The argument principle connects the winding number of a curve with the number of zeros and poles inside the curve. This principle is useful for mathematical applications where we want to locate the zeros and poles.

Assumption 1. Note that this research project will be looking specifically at holomorphic functions, hence the number of poles will be 0. Therefore, the argument principle will be simplified to exclusively locate zeros and not poles.

1.2 Argument Principle

The argument principle relates the difference between the number of zeros of a holomorphic function to a contour integral of the function's logarithmic derivative. The contour integral $\oint_C \frac{f'(z)}{f(z)} dz$ can be interpreted as $2\pi i$ times the winding number of the path $f(C)$ around the origin. That is, it is i times the total change in the argument of $f(z)$ as z travels around C , explaining the name of the theorem.

Theorem 2. *Argument Principle. If $f(z)$ is a holomorphic function inside and on some closed contour C , and f has no zeros on C , then*

$$\frac{1}{2\pi i} \oint_C \frac{f'(z)}{f(z)} dz = Z$$

where Z denote the number of zeros of $f(z)$ inside the contour C , with each zero counted as many times as its multiplicity and order.

For better understanding, this paper provides the definition of winding numbers, holomorphic functions, zeros, and contour integrals.

1.3 Supplementary Definitions

Definition 3. Winding numbers. The winding number of a closed curve in the plane around a given point is an integer representing the total number of times that curve travels counterclockwise around the point.

Let's take a look at an example for better understanding of winding numbers and the use of the argument principle.

Problem 4. Winding numbers. Let $f(z) = z^2 + z$. Find the winding number of $f \circ \gamma$ around 0 for $\gamma_1 =$ circle of radius 2, $\gamma_2 =$ circle of radius $\frac{1}{2}$, and $\gamma_3 =$ circle of radius 1.

$f(z) = z(z + 1)$ has zeros at 0 and -1 .

1. For γ_1 , there are two zeros of both 0 and -1 .
2. For γ_2 , there is one zero of 0.
3. For γ_3 , there is one zero of 0. -1 is not inside the circle, therefore it does not count.

Definition 5. Holomorphic function. A holomorphic function is a complex-valued function of one or more complex variables that is, at every point of its domain, complex differentiable in a neighborhood of the point.

Definition 6. Meromorphic function. A meromorphic function on an open subset D of the complex plane is a function that is holomorphic on all of D except for a set of isolated points, which are poles of the function.

Definition 7. Zeros. Zeros of holomorphic functions are points z where

$$f(z) = 0.$$

Definition 8. Contour integral. Contour integration is a method of evaluating certain integrals along the paths in the complex plane. For continuous functions in the complex plane, the contour integral can be defined in analogy to the line integral by first defining the integral along a directed smooth curve in terms of an integral over a real valued parameter.

Notation 9. Contour integral. Contour integrals are denoted by \oint .
